

PICKUP HEIGHT ADJUSTMENT

It is important to mount the face of the pickup as close to the strings as possible in order to achieve the highest output level with the lowest background noise. There are three different shim thickness options included, each with a left and right side.

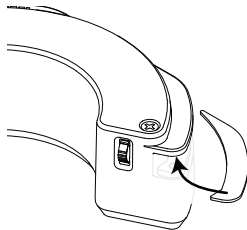

First, fit the pickup into the guitar as described in the Quick Install or Permanent Installation sections in the User Guide or on fishman.com.

Then, determine if you need to add shims by depressing the strings at the top-most fret, checking the gap between each string and the face of the pickup housing.

The goal is to minimize this gap as much as possible while not interfering with the instrument's playability.

If there is a large enough gap where a shim can be used, loosen the clamps and move the pickup off the guitar top. Add one shim to each side as shown. Test-fit each shim size first before removing the shim's adhesive cover then stick them to the pickup housing.
